CS 35L

Software Construction Laboratory

Lecture 3.2

24th January, 2019

Logistics

- ▶ Hardware requirement for Week 8
 - ▶ Seeed Studio BeagleBone Green Wireless Development Board
- ▶ Presentations for Assignment 10
 - ▶ Fill your details in the link below
 - ▶ Do not fill a slot without a Presentation Topic
 - ▶ https://docs.google.com/spreadsheets/d/1o6r6CKCaB2du3klPflHiquymhBvbn7oP0wkHHMz_q1E/edit?usp=sharing

Review - Previous Lab

- ▶ Modifying large-scale software
- ▶ Decompressing files
- ▶ Compilation process
- ▶ Make

The background features abstract, overlapping green geometric shapes, primarily triangles and polygons, in various shades of green, creating a modern and dynamic visual effect. The word "Python" is centered in a bold, green, sans-serif font.

Python

What is Python?

- ▶ Not just a scripting language
- ▶ Object-Oriented language
 - ▶ Classes
 - ▶ Member functions
- ▶ Compiled and interpreted
 - ▶ Python code is compiled to bytecode
 - ▶ Bytecode interpreted by Python interpreter
- ▶ Not as fast as C but easy to learn, read and use
- ▶ Very popular at Google and other big companies

Why is it Popular?

- ▶ Uses English keywords frequently where other use different punctuation symbols
- ▶ Fewer Syntactical Constructions
- ▶ Automatic Garbage Collection
- ▶ Easy integration with other programming languages

Different Modes

- ▶ Interactive:
 - ▶ Run commands on the python shell without actually writing a script/program.
- ▶ Script Mode:
 - ▶ Type a set of commands into a script
 - ▶ Execute all the commands at once by running the script

Python Variables

- ▶ Case sensitive
- ▶ Start with _ (underscore) or letters followed by other letters, underscores or digits
- ▶ Other special characters are not allowed as part of the variable name
- ▶ Certain reserved words may not be used as variable names on their own unless concatenated with other words

Example - Python Variables

```
#!/usr/bin/python  
counter = 100    # An integer assignment  
miles = 1000.0   # A floating point  
name = "John"    # A string  
print counter  
print miles  
print name
```

- ▶ Output:
 - ▶ 100
 - ▶ 1000.0
 - ▶ John

Python Lines and Indentation

- ▶ No braces to indicate blocks of code for class and function definitions or flow control
- ▶ Blocks of code are denoted by line indentation, which is why it is strictly enforced
- ▶ Number of spaces for indentation may be variable but all the statements within the same block must be equally indented
- ▶ Hence, a single space has the ability to change the meaning of the code

Python Decision Making

```
#!/usr/bin/python  
var = 100  
if ( var == 100 ) :  
    print "Correct"  
print "Good bye!"
```

Python List

- ▶ Common data structure in Python
- ▶ A python list is like a C array but much more:
 - ▶ Dynamic (mutable): expands as new items are added
 - ▶ Heterogeneous: can hold objects of different types
- ▶ How to access elements?
 - ▶ `List_name[index]`

Example

- ▶ `>>> t = [123, 3.0, 'hello!']`
- ▶ `>>> print t[0]`
 - ▶ 123
- ▶ `>>> print t[1]`
 - ▶ 3.0
- ▶ `>>> print t[2]`
 - ▶ hello!

Example - Merging Lists

- ▶ `>>> list1 = [1, 2, 3, 4]`
- ▶ `>>> list2 = [5, 6, 7, 8]`
- ▶ `>>> merged_list = list1 + list2`
- ▶ `>>> print merged_list`
 - ▶ Output: `[1, 2, 3, 4, 5, 6, 7, 8]`

Python Dictionary

- ▶ Essentially a hash table
 - ▶ Provides key-value (pair) storage capability
- ▶ Instantiation:
 - ▶ `dict = {}`
 - ▶ This creates an EMPTY dictionary
- ▶ Keys are unique, values are not!
 - ▶ Keys must be immutable (strings, numbers, tuples)

Example - Python Dictionary

```
dict = {}  
dict['france'] = "paris"  
dict['japan'] = "tokyo"  
print dict['france']
```

```
dict['germany'] = "berlin"  
if (dict['france'] == "paris"):  
    print "Correct!"  
else:  
    print "Wrong!"
```

```
del dict['france']  
del dict
```

For loops

```
list1 = ['Mary', 'had', 'a', 'little', 'lamb']
```

```
for i in list1:  
    print i
```

Result:

Mary
had
a
little
lamb

```
for i in range(len(list1)):  
    print i
```

Result:

0
1
2
3
4

Optparse Library

- ▶ Powerful library for parsing command-line options
 - ▶ Argument:
 - ▶ String entered on the command line and passed in to the script
 - ▶ Elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed)
 - ▶ Option:
 - ▶ An argument that supplies extra information to customize the execution of a program
 - ▶ Option Argument:
 - ▶ An argument that follows an option and is closely associated with it. It is consumed from the argument list when the option is

I/O Basics

- ▶ The `raw_input([prompt])` function reads one line from standard input and returns it as a string (removing the trailing newline)
 - ▶ `str = raw_input("Enter your input: ")`
 - ▶ `print "Received input is : ", str`
- ▶ The `input([prompt])` function is equivalent to `raw_input`, except that it assumes the input is a valid Python expression and returns the evaluated result to you.
 - ▶ `str = input("Enter your input: ")`
 - ▶ `Print "Received input is : ", str`

Functions

- ▶ A function is a block of organized, reusable code that is used to perform a single, related action. They provide better modularity for your application and a high degree of code reusing.
- ▶ Syntax:
 - ▶ `def function_name(parameters):`
 - ▶ `#code inside the function`

Functions - examples

- ▶ Example 1:
 - ▶ `def printme(new_string):` #string is a parameter
 - ▶ `#This prints a passed string into this function`
 - ▶ `print new_string`
 - ▶ `return`
- ▶ Example 2: To print sum of numbers in a list
 - ▶ `def find_sum(new_list):`
 - ▶ `sum=0 #initialize variable*`
 - ▶ `for element in new_list:`
 - ▶ `sum = sum + element`
 - ▶ `return sum #returns the computed sum`
- ▶ `answer_variable=find_sum([2,3,4,5])` #function call
- ▶ `print answer_variable`
- ▶ `* #` are used for putting comments

Task 1

- ▶ Take a list `a = [1,1,2,3,5,8,13,21,34,55,89]` and write a program that prints out all the elements of the list that are less than 5
- ▶ Instead of printing the elements one by one, make a new list that has all the elements less than 5 from this list in it and print out this new list.
- ▶ Ask the user for a number and return a list that contains only elements from the original list `a` that are smaller than that number given by the user

Task 2

- ▶ Write a Python program to get a string made of the first 2 and the last 2 chars from a given a string.
 - ▶ Sample String : 'w3resource'
 - ▶ Expected Result : 'w3ce'
 - ▶ Sample String : 'w3'
 - ▶ Expected Result : 'w3w3'

Task 3

- ▶ Create a python dictionary with the following keys and values:
- ▶ “Names” : [“Mickey”, “Minnie”]
- ▶ “Mickey” : [“UCLA”, “Bachelor Degree”]
- ▶ “Minnie” : [“UCB”, “Bachelor Degree”]
- ▶ The values in the dictionary are in the form of a list.
 - ▶ Now traverse the list whose key is ‘Names’ and for every element in this list, find the corresponding key (eg. ‘Mickey’). Append the word “Computer Science” to the value (eg. the list of ‘Mickey’) of that particular key.
 - ▶ Now create a new key-value pair for “DonaldDuck” - [“Stanford”, “PhD”, “Computer Science”]. Add the name ‘DonaldDuck’ to the ‘Names’ list as well.

Assignment 3 - Homework Hints

- ▶ If you are unsure of how something should be output, run a test using existing shuf utility!
 - ▶ Create your own test inputs
- ▶ The shuf option --repeat is Boolean
 - ▶ Which action should you use?
- ▶ Q4: Python 3 vs. Python 2
 - ▶ Look up “automatic tuple unpacking”
- ▶ Python 3 is installed in /usr/local/cs/bin
 - ▶ export PATH=/usr/local/cs/bin:\$PATH

Questions?
