Winter 19

TA: Guangyu Zhou

Digital Signature

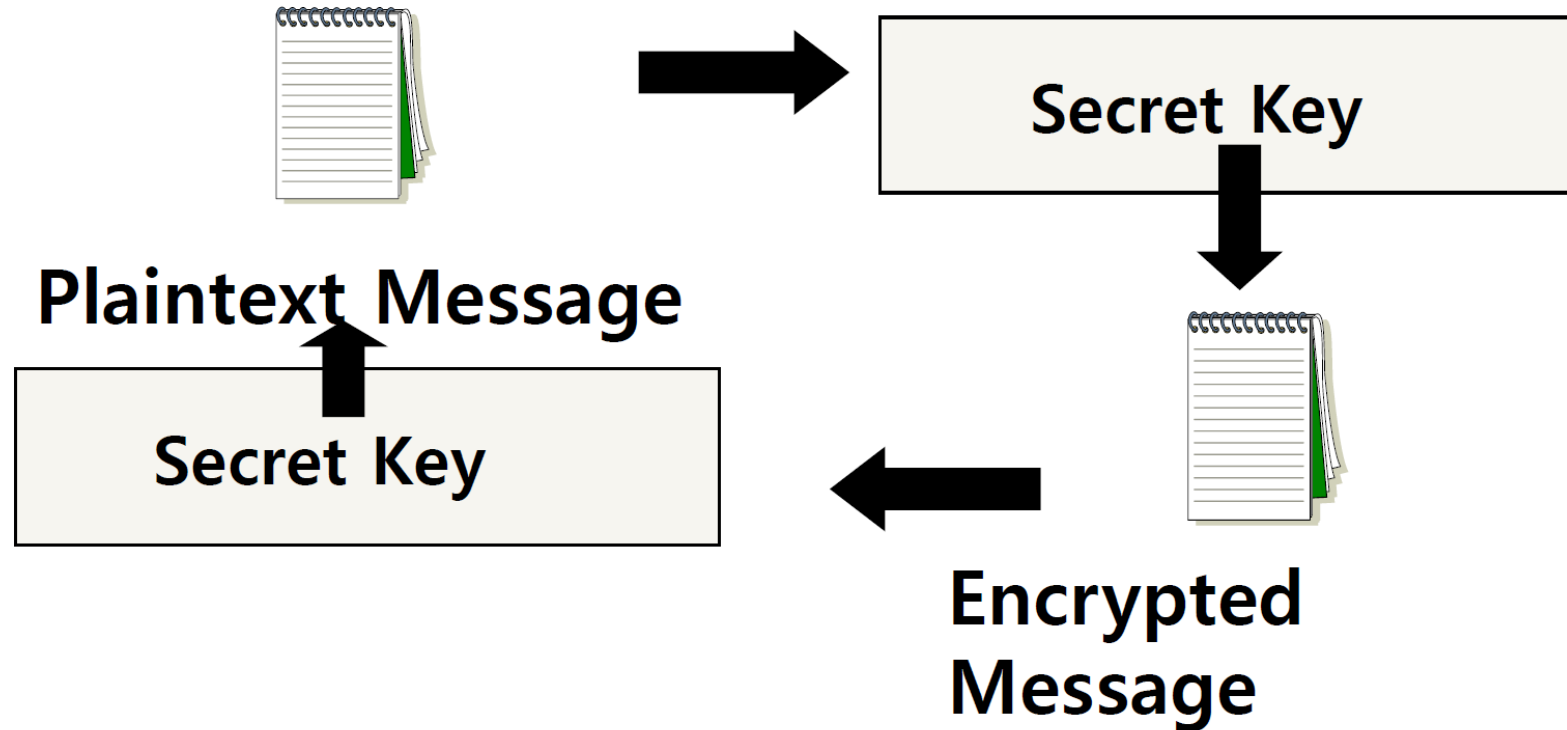

Week 9

Outline

- Review of Cryptography
 - Digital Signature
 - Hints for Assignment 8
-

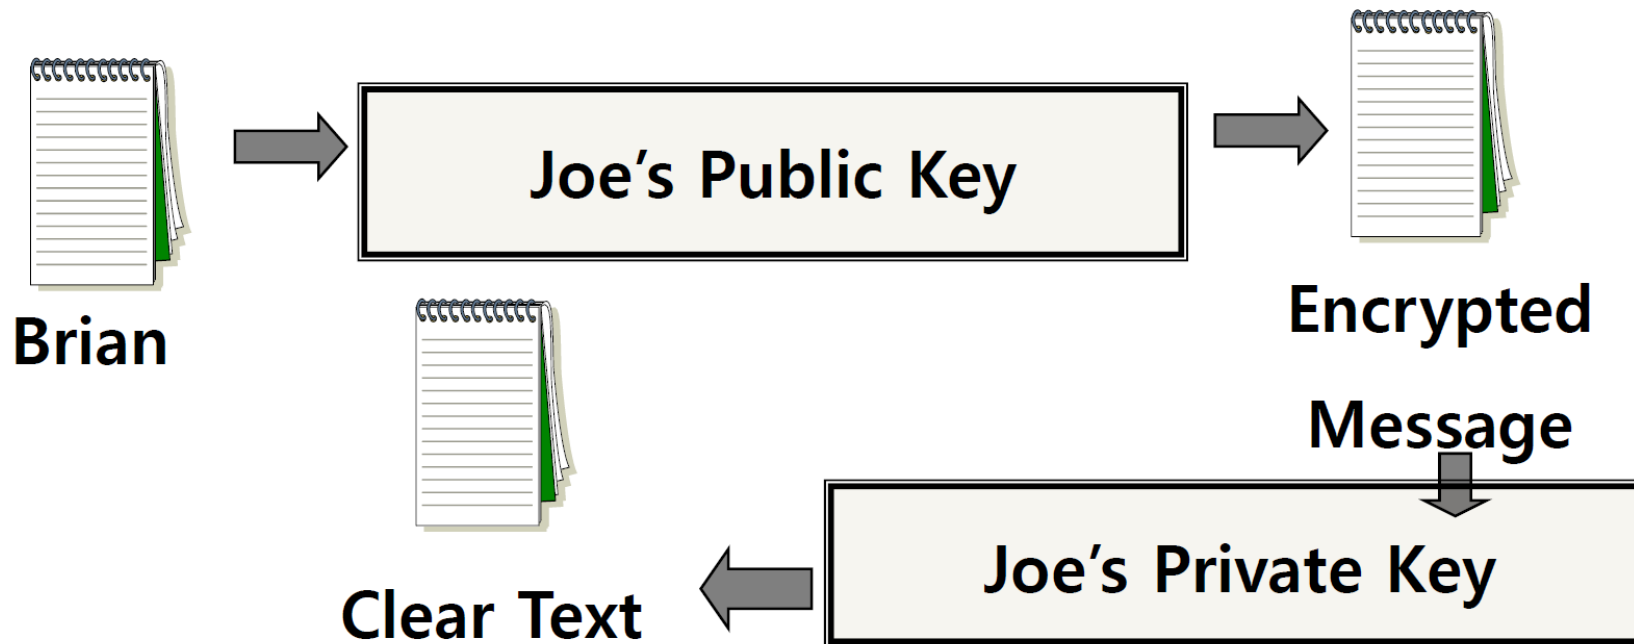

Review: Secret Key (symmetric) Cryptography

- A single key is used to both encrypt and decrypt a message

Review: Public Key (asymmetric) Cryptography

- Two keys are used: a public and a private key. If a message is encrypted with one key, it has to be decrypted with the other.

Review: Encryption Types Comparison

- Symmetric Key Encryption
 - a.k.a shared/secret key
 - Key used to encrypt is the same as key used to decrypt
 - Asymmetric Key Encryption: Public/Private
 - 2 different (but related) keys: public and private. Only creator knows the relation. Private key cannot be derived from public key
 - Data encrypted with public key can only be decrypted by private key and vice versa
 - Public key can be seen by anyone
 - **Never** publish private key!!!
-

Review: User Authentication

- Password-based authentication
 - Prompt for password on remote server
 - If username specified exists and remote password for it is correct then the system lets you in
 - **Key-based authentication**
 - Generate a key pair on the client
 - Copy the public key to the server (`~/.ssh/authorized_keys`)
 - Server authenticates client if it can demonstrate that it has the private key
 - The private key can be protected with a passphrase
 - Every time you ssh to a host, you will be asked for the passphrase (inconvenient!)
-

Digital signature

- Protect **integrity** of the documents
 - Receiver received the document that the sender intended
=> An electronic stamp or seal, almost exactly like a written signature, except more guarantees!
 - Digital signature is extra data attached to the document (or separately) that can be used to check **tampering**
 - Message digest
 - Shorter version of the document
 - Generated using **hashing** algorithms
 - Even a slight change in the original document will change the message digest with **high probability**
-

Steps for Generating a Digital Signature

SENDER:

- 1) Generate a *Message Digest*
 - The message digest is generated using a set of hashing algorithms
 - A message digest is a 'summary' of the message we are going to transmit
 - Even the slightest change in the message produces a different digest
 - 2) Create a Digital Signature
 - The message digest is encrypted using the sender's *private* key. The resulting encrypted message digest is the *digital signature*
 - 3) Attach digital signature to message and send to receiver
-

Steps for Generating a Digital Signature

RECEIVER:

- 1) Recover the *Message Digest*
 - Decrypt the digital signature using the sender's public key to obtain the message digest generated by the sender
 - 2) Generate the Message Digest
 - Use the same message digest algorithm used by the sender to generate a message digest of the received message
 - 3) Compare digests (the one sent by the sender as a digital signature, and the one generated by the receiver)
 - If they are not *exactly the same* => the message has been tampered with by a third party
 - We can be sure that the digital signature was sent by the sender (and not by a malicious user) because *only* the sender's public key can decrypt the digital signature and that public key is proven to be the sender's through the certificate. If decrypting using the public key renders a faulty message digest, this means that either the message or the message digest are not exactly what the sender sent.
-

Digital signature

Verifies document integrity, but does it prove origin? and who is the Certificate Authority?

What is *GNU privacy guard*

- GnuPG allows you to encrypt and sign your data and communications
 - It features a versatile key management system, along with access modules for all kinds of public key directories.
 - GnuPG, also known as *GPG*, is a command line tool with features for easy integration with other applications.
 - Reference: <https://gnupg.org/gph/en/manual.html#INTRO>
-

GNU privacy guard (> gpg [option])

--gen key	generating new keys
--armor	ASCII format
--export	exporting public key
--import	import public key
--detach-sign	creates a file with just the signature
--verify	verify signature with a public key
--encrypt	encrypt document
--decrypt	decrypt document
--list-keys	list all keys in the keyring
--send-keys	register key with a public server/-keyserver option
--search-keys	search for someone's key

Hints for homework 8

- Do homework 8 on Inxsr, not on your Beaglebone board
 - Answer 2 questions in the file hw.txt
 - A file eeprom that is a copy of the file /sys/bus/i2c/devices/0-0050/eeprom on your BeagleBone.
 - <https://www.gnupg.org/gph/en/manual.html>
 - Generate a key pair with the GNU Privacy Guard's commands (choose default options when prompted)
 - Export public key, in ASCII format, into hw-pubkey.asc
 - Use the private key you created to make a detached clear signature eeprom.sig for eeprom
 - Use given commands to verify signature and file formatting (assignment specs)
-
